#### Aim: How can we tell if a substance is a compound?

<u>Compound</u> a substance composed of **2 or more elements chemically** combined. Compounds consist of 2 or more types of atoms bonded to each other.

Element A Element B Compd AB Compd A2B

### 1<sup>st</sup> - Just check out the formula.

Cu, C, Na, Fe, H<sub>2</sub>,O<sub>2</sub>,...only **one** symbol, elements

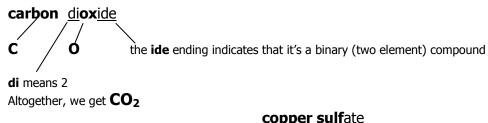

NaCl, CuO, KBr, H<sub>2</sub>O... **two or more** symbols written, side by side, compounds

**And,**  $H_2O \neq H_2O_2$ 

Compounds have specific formulas & definite compositions.

## 2<sup>nd</sup>- Analyze the name.

You can tell from the name that it's a compound. You'll see pieces of the names of elements that make up the compound and prefixes & endings that tie it altogether.

Cu S See Table E,

ate indicates that **O** is present

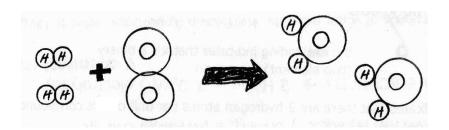

Altogether, we get **CuSO**<sub>4</sub>

# 3<sup>rd</sup>- Compare the properties.

When elements are chemically combined their properties change. For example,

$H_2$	$O_2$	H₂O
Hydrogen	Oxygen	Water
(g)	(g)	(/)
explosive	flammable	non-explosive
		non-flammable

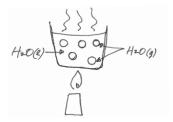

**WHY???** the properties don't "cancel out"; they change due to the **breaking of bonds**, **rearrangement of atoms** & **formation of new bonds**. That's what a chemical change (reaction) is all about.

# 4<sup>th</sup> - Try breaking it down.

Compounds are formed **and** decomposed only by a chemical change.

$$H_2O(/) + HEAT \rightarrow H_2O(g)$$
 } boiling, **physical** change

**2** 
$$H_2O(/)$$
 + ELECTRICITY  $\rightarrow$  **2**  $H_2(g)$  + **1**  $O_2(/)$  } electrolysis, **chemical** change

Demo: Electrolysis of water using the **Hoffmann Apparatus**; refer to Diagram in handout (HW sheet).

**NOTE:** a) H<sub>2</sub> collects at the (-) electrode; O<sub>2</sub> at the (+) electrode

- b) H<sub>2</sub> collects twice as much as O<sub>2</sub> and
- c) H<sub>2</sub> "pops" with a burning splint;
- d) O<sub>2</sub> "ignites" with a glowing splint.
